# *Towards the Construction of Global IPv6 Hitlist and Efficient Probing of IPv6 Address Space*

**Guanglei Song, Lin He, Zhiliang Wang,**

**Jiahai Yang, Tao Jin, Jieling Liu, Guo Li**

*Institute for Network Sciences and Cyberspace, Tsinghua University  
Beijing National Research Center for Information Science and Technology*

## ■ Motivations

With the growing address exhaustion of IPv4 , IPv6 is being deployed increasingly commonly around the world, and **this trend will accelerate.**

### IPv6 Adoption

We are continuously measuring the availability of IPv6 connectivity among Google users. The graph shows the percentage of users that access Google over IPv6.

Source: <https://www.google.com/intl/en/ipv6/statistics.html>

## ■ Motivations

- Various IPv6 address configuration methods
- Vast IPv6 space
- Low address usage

Scanning all IPv4 address space only needs tens of minutes

Scanning all IPv6 address space needs more than **1 million years**

Brute-force scanning of all IPv6 space is infeasible

How to quickly find active IPv6 addresses in limited probe resources?

## ■ Motivations

Learn structure of  
seed addresses

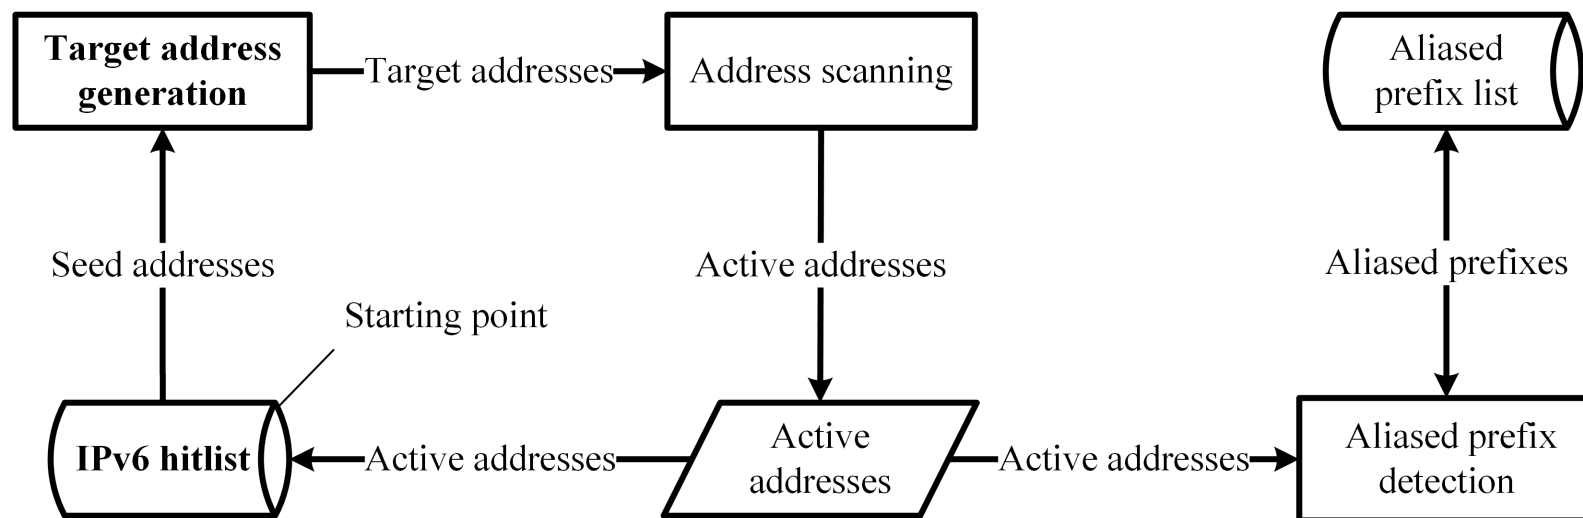

Looking for a needle in the haystack

Looking for a needle in the pond

### **solution:**

learn structure of seed address space to reduce the probing scope and generate candidate addresses that may have a higher probability to be active.

## ■ Motivations

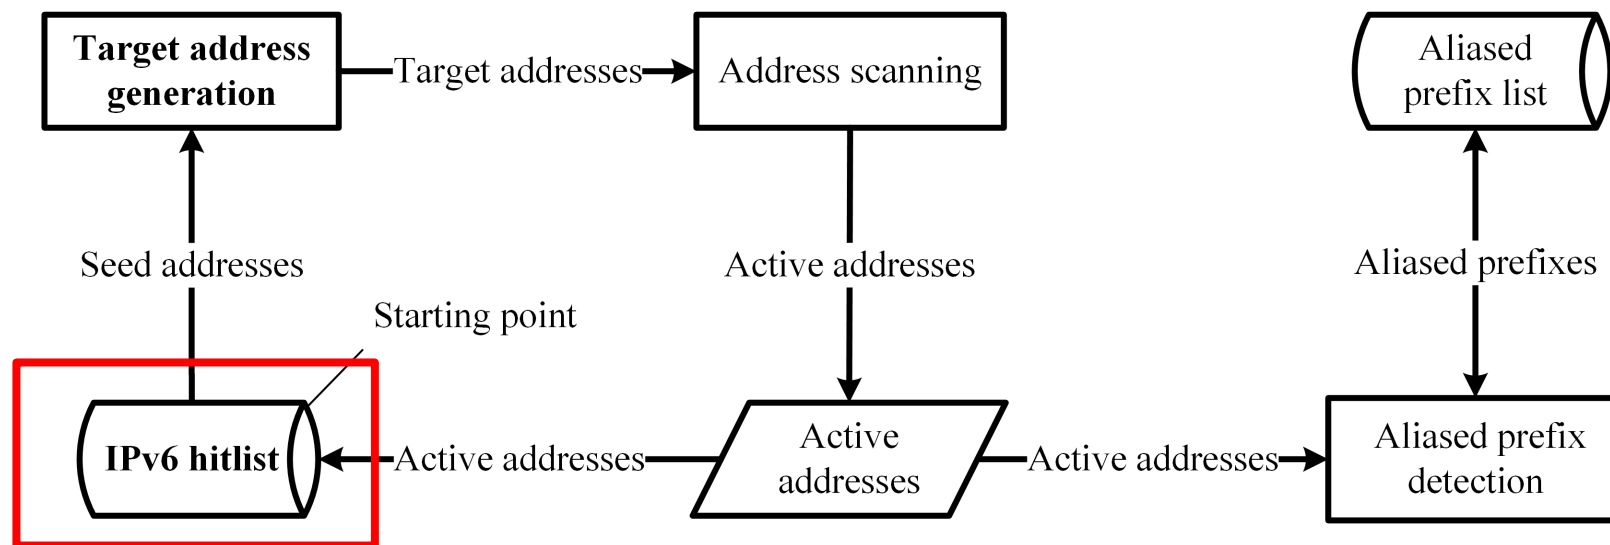

Framework of IPv6 address probing

*Hitlist : IPv6 address list extracted from multiple data sources*

*Seed addresses: Active address as input of address generation algorithms*

*Target address: Possible active address generated by a address generation algorithm*

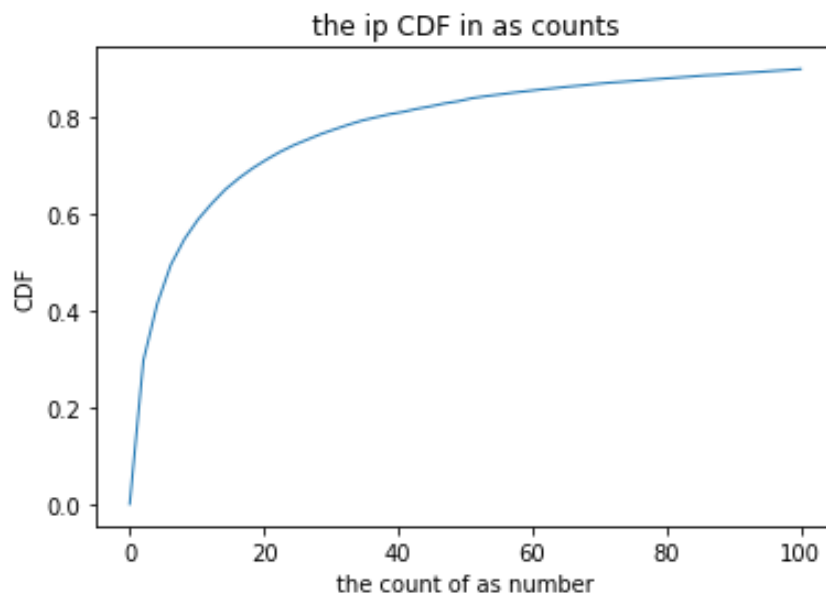

## ■ Motivations

Framework of IPv6 address probing

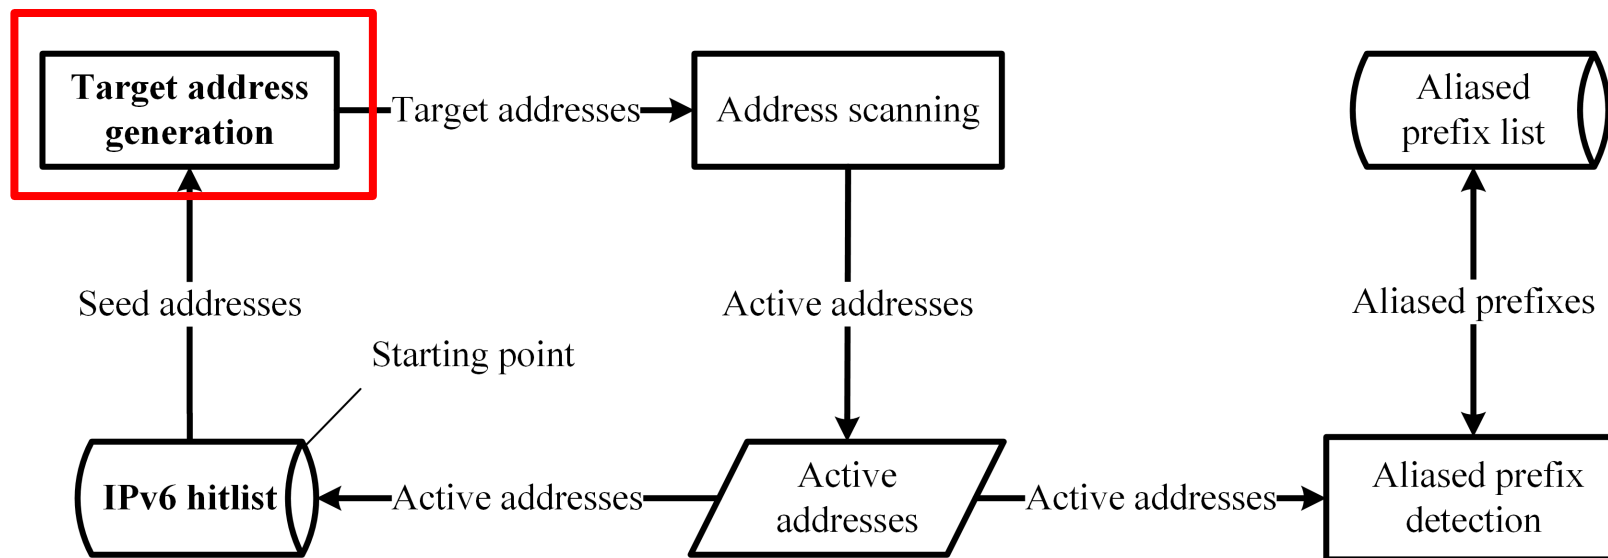

## ■ Motivations

**Challenge 1 :** Uneven distribution and small quantity of public IPv6 hitlist.

Can we construct greater quantity and higher quality of IPv6 hitlist ?

## ■ Motivations

Framework of IPv6 address probing

## ■ Motivations

**Challenge 2:** Inefficient the state-of-the-art algorithms of address generation

method	cluster-time	hit-rate <sup>1</sup>	limitation
Entropy/IP	slow	Low(<1%)	small detection scale
6Gen	slow ( $O(n^3)$ )	Low(<15%)	small detection scale
6Tree	first ( linear time )	Low(<17%)	limit the scope under same budget

hit-rate<sup>1</sup> : Generate 50M candidate addresses

Can we design address generation algorithm with faster time and higher hit-rate ?

## ■ IPv6 Hitlist

Building greater quantity and higher quality of IPv6 hitlist from multiple sources.

1. **Public:** extract IPv6 addresses based on the data sources from December 4th, 2019 to February 10th 2020.
2. **Active:** obtain IPv6 addresses in each BGP prefix by Random-Bytes from October 1st, 2019 to January 31st, 2020.
3. **Passive:** mirror NetFlow traffic from the CERNET2 and extract IPv6 addresses from August 1st, 2019 to December 31st, 2019.
4. **TraceIP:** use scamper to perform traceroute measurement on the IPv6 addresses.

## ■ IPv6 Hitlist

### OVERVIEW OF OUR IPV6 HITLIST ON FEBRUARY 16, 2020

Name	Nature	IPs	#ASes	#PFXes	#PFXes <sup>1</sup>
Public	Mixed	61M	12.4k	26.3k	25.1k
Active	Mixed	870M	14.1k	35.3k	34.1k
Passive	Mixed	340M	4.2k	8.3k	7.6k
TraceIP	Routes	49M	8.5k	12.6k	11.7k
<b>Total</b>	<b>Mixed</b>	<b>1.3B</b>	<b>16.5k</b>	<b>45.2k</b>	<b>44.1k</b>

#PFXes<sup>1</sup> : Removing aliased prefixes using aliased prefix detection

Mixed : Address types include client, server, router, etc

## *Talk Outline*

- IPv6 hitlist
- **DET: IPv6 Address Generation Algorithm**
- Evaluation About IPv6 hitlist And DET
- Summary

## ■ DET: IPv6 Address Generation Algorithm

- **Characteristics**

Hierarchical characteristic (6Tree) + Distribution characteristic (6Gen)

- **Assumption**

High-density regions of seeds are associated with high-density regions of active addresses.

- **Address vectorization**

`2605:bb00:8100:0100:0001:0010:0000:0010` eg. hex `2605bb00810001000001001000000010`

How to quickly discover high-density regions of addresses ?

## *Discover high-density regions*

- **Density Space Tree**

root node: represents the entire seed address space

leaf node: represents a high-density region

Storage address hierarchy and distribution characteristics

- **Cluster**

top-down divisive hierarchical clustering (DHC)

- **Splitting Indicator: The Smallest Entropy**

Node split at the position with the smallest entropy value. Theoretical proof in paper

Ensure that high-density regions are at the leaf

# Density Space Tree Generation

## ■ Evaluation About IPv6 Hitlist

### COMPARISON OUR HITLIST AND GASSER'S HITLIST IN ADDRESS DISTRIBUTION

Hitlist	IPs	#ASes	#PFXes	#PFXes <sup>1</sup>
Oliver's hitlist	61M	12.4k	26.3k	25.1k
<b>Our hitlist</b>	<b>1.3B</b>	<b>16.5k</b>	<b>45.2k</b>	<b>44.1k</b>

#PFXes<sup>1</sup> : Removing aliased prefixes using aliased prefix detection

Fig. 2. Prefix distribution of two hitlists

*nd\_stable*: address is continuously active for *n* days

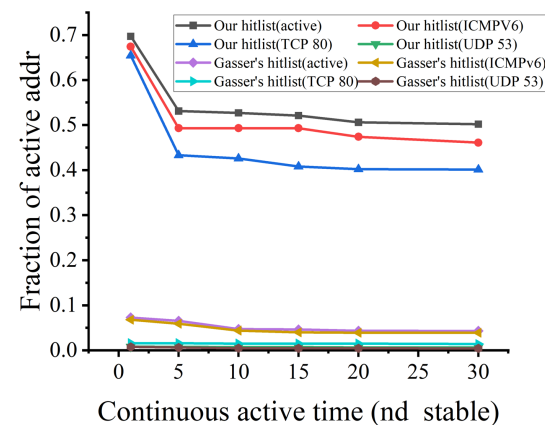

Fig. 3. Active address stability of two hitlists

## *Talk Outline*

- IPv6 hitlist
- DET: IPv6 Address Generation Algorithm
- **Evaluation About IPv6 hitlist And DET**
- Summary

## ■ Evaluation About DET

### Target Generation Efficiency

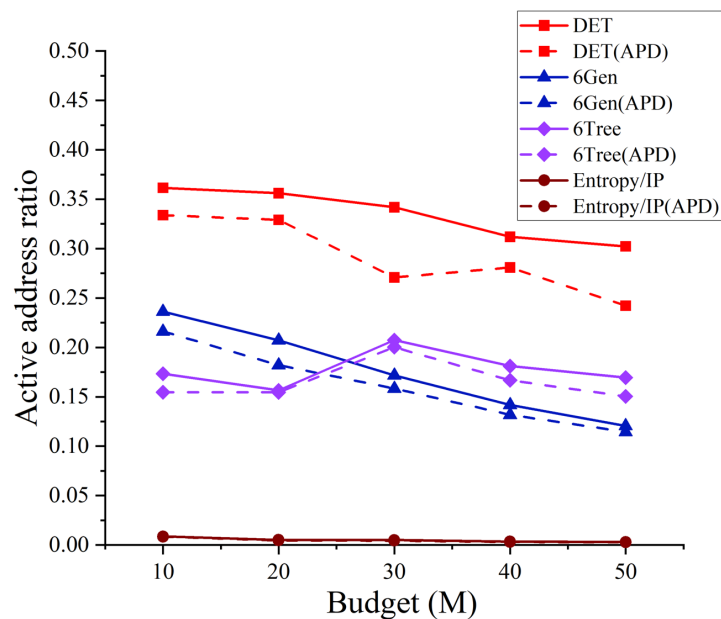

Fig. 4. Target generation in announced prefixes

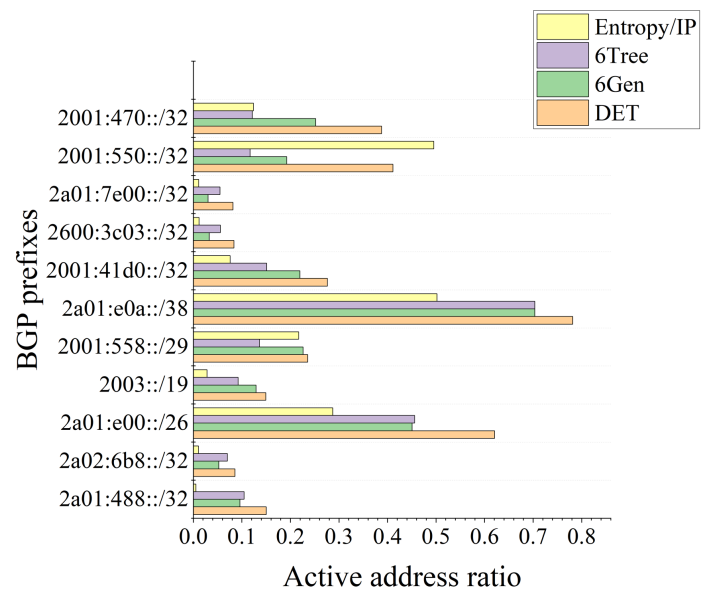

Fig. 5. Target generation in announced prefixes

*Budget: the probing number of target addresses*

## ■ Evaluation About DET

### DHC Time Performance

DET learns the distribution characteristics in **linear time**

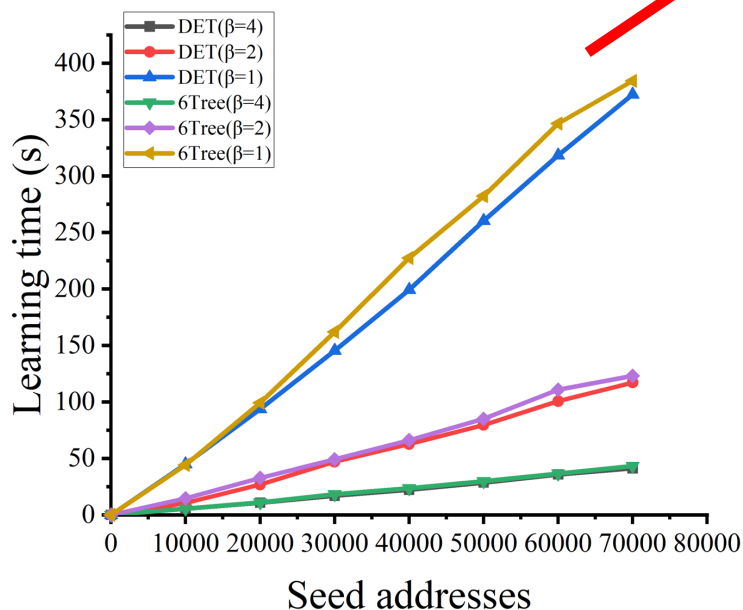

Fig. 6. DET VS 6Tree (DHC)

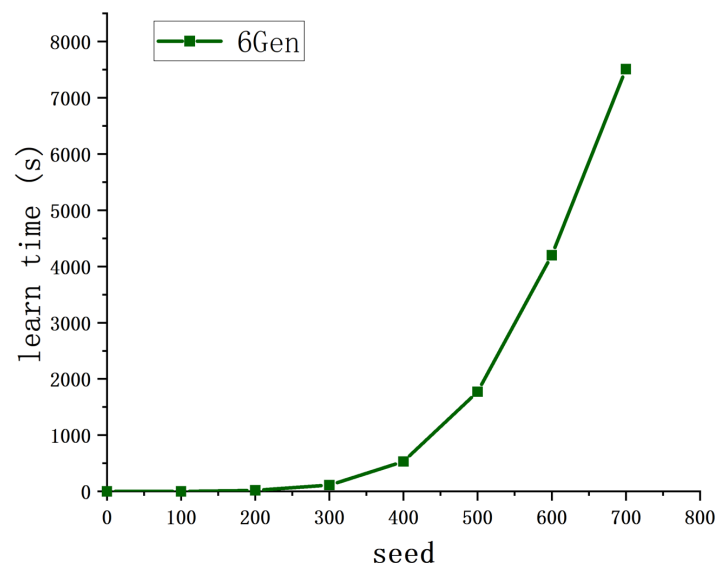

Fig. 7. 6Gen density clustering (AHC)

## *Talk Outline*

- IPv6 hitlist
- DET: IPv6 Address Generation Algorithm
- Evaluation About IPv6 hitlist And DET
- Summary

## ■ Summary

### ● Hitlist

1. Greater quantity and higher quality of IPv6 hitlist
2. Maintain address fingerprint information

### ● DET

1. Faster time performance of address cluster
2. Higher IPv6 active address hit rate

Support IPv6 network measurement like IPv4

Further open the door to explore security issues on IPv6
